

LINGI2261: Artificial Intelligence

Assignment 1: Solving Problems with Uninformed Search

Gaël Aglin, Alexander Gerniers, Yves Deville
February 10, 2021

Guidelines

- This assignment is due on **Thursday 25 February, 18:00**.
- *No delay* will be tolerated.
- *Document* your source code (at least the difficult or more technical parts of your programs). Python docstrings for important classes, methods and functions are also welcome.
- Copying code or answers from other groups (or from the internet) is strictly forbidden. Each source of inspiration must be clearly indicated.
- Source code shall be submitted on the online *INGInious* system. Only programs submitted via this procedure will be graded. No program sent by email will be accepted.
- Respect carefully the *specifications* given for your program (arguments, input/output format, etc.) as the program testing system is *fully automated*.
- The answer to questions must be given by filling in the latex template provided. The final file must be submitted on *gradescope*. No report sent by email will be accepted.
- Nothing must be modified in the template except your answer that you insert in the *answer* environments as well as your names and your group number. The names are provided through the command *students* while the command *group* is used for the group number. The dimensions of *answer* fields *must not* be modified either. For the tables, put your answer between the "&" symbols. Any other changes to the file will *invalidate* your submission.
- To submit on gradescope, go to <https://gradescope.com> and click on the "log in" button. Then choose the "school credentials" option and search for *UCLouvain Username*. Log in with your global username and password. Find the course LINGI2261 and the Assignment 1, then submit your report. Only one member should submit the report and add the second as group member.
- For those who have not been automatically added to the course, at the right bottom of gradescope homepage, click on "Enroll on course" button and type the code *86KJVB*.
- Check this link if you have any trouble with group submission <https://help.gradescope.com/article/m5qz2xsnjy-student-add-group-members>

Deliverables

- The following files are to be submitted:
 - knight.py (*INGInious*): The file containing your implementation of the Knight's tour solver. Your program should take four arguments. The first two are respectively the number of rows and the number of columns of the chessboard while the last two represent respectively y and x coordinates of the starting position of your knight. It should print a solution to the problem to the standard output, respecting the format described further. The file must be encoded in **utf-8**.
 - report_A1_group_XX.pdf (*Gradescope*): Answers to all the questions using the provided template. Remember, the more concise the answers, the better.

Anti plagiat charter

As announced in the class, you'll have to electronically sign an anti plagiat charter. This should be done **individually** in the **INGInious** task entitled *Assignment 1: Anti plagiat charter*. Both students of a team must sign the charter.

Important

- For the implementation part of the assignment, you are required to use *Python 3*
- Python 3.9.1 can be downloaded at <https://python.org/downloads/>
- On your computer, after installing Python 3, you will be able to launch your programs using `python3 <your_program>`
- In the labs, you can find Python 3 under `/opt/python3/bin/python3`. You can of course add `/opt/python3/bin` to your PATH to be able to launch your programs using `python3 <your_program>`.
- Python 3 documentation can be found at <http://docs.python.org/py3k/>
- The assignment must be submitted via the *INGInious* tool. You first have to *create groups of two*. Only then you will be granted access to the submission tool. The procedure to register and submit your hard work is described below. *Don't wait until the last minute* to create your group and to familiarize with the tool.
- If you want to ask us questions, we are available on Teams (Aglin Frédéric) on Tuesdays from 2:30pm to 4:30pm. *For general questions, do not hesitate to use the forum set up especially for this assignment, on Moodle.*

Submitting your programs

Python programs must be submitted on the INGInious website: <https://inginius.info.ucl.ac.be>. In order to do so, you must first create groups of two. To do so, assign yourself in an available group on the INGInious page of the course. Inside INGInious, you can find different courses. Inside the course 'LINGI2261: Artificial Intelligence', you will find the

tasks corresponding to the different assignments due for this course. The task at hand for this assignment is *Assignment 1: Knight's tour* . In the task, you can submit your program (one python file containing the knight's tour solver, encoded in utf-8). Once submitted, your program will immediately be evaluated on the set of given instances and also on a hidden set of instances. The results of the evaluation will be available directly on INGINious. You can, of course, make as many submissions as you want. For the grade, only the best submission will be considered. You thus know the grade you will receive for the program part of the assignment! If you have troubles with INGINious, use the assignment forum on Moodle.

Important

Although your programs are graded automatically, they will still be checked for plagiarism !

1 Python AIMA (3 pts)

Many algorithms of the textbook "AI: A Modern Approach" are implemented in Python. Since you are required to use Python 3, we will provide a Python 3 compliant version of the AIMA library. The Python modules can be downloaded on Moodle in the folder *Assignment 1* of S2. All you have to do is to decompress the archive of aima-python3 and then put this directory in your python path: `export PYTHONPATH=path-to-aima-python3`. As we will use our own version of the library to test your programs, no modification inside the package is allowed.

The objective of these questions is to read, understand and be able to use the Python implementation of the *uninformed methods* (inside *search.py* in aima-python3 directory).

Questions

1. In order to perform a search, what are the classes that you must define or extend? Explain precisely why and where they are used inside a *tree_search*. Be concise! (e.g. do not discuss unchanged classes).
2. Both *breadth_first_graph_search* and *depth_first_graph_search* are making a call to the same function. How is their fundamental difference implemented (be explicit)?
3. What is the difference between the implementation of the *graph_search* and the *tree_search* methods and how does it impact the search methods?
4. What kind of structure is used to implement the *closed list*? What properties must thus have the elements that you can put inside the closed list?
5. How technically can you use the implementation of the closed list to deal with symmetrical states? (hint: if two symmetrical states are considered by the algorithm to be the same, they will not be visited twice)

2 The Knight's tour Problem (17 pts)

The initial configuration is represented by a grid of shape $nrows \times ncols$ and a knight at its initial position index $[i][j]$ in the grid. i represents the rows axis while j represents the columns

axis. The $[0][0]$ position is on the top left corner. You have to move the knight following the moves of a knight is a chess game such that all the cases of the chessboard must be visited only once. Figure 1b shows for the black knight all possible moves. Depending of the position of the white knight only four moves are possible. You can get more information on a knight moves on [https://en.wikipedia.org/wiki/Knight_\(chess\)](https://en.wikipedia.org/wiki/Knight_(chess)). In summary, a “knight’s tour” is a sequence of moves of a knight on a chessboard such that the knight visits every square only once¹.

(a) Screenshot of a complete 8×8 Knight's tour game interface. Each red cross is a visited tile.

(b) Screenshot of a knight's moves on a 8×8 chessboard. Each cross is a possible move.

Figure 1: Illustrations of Knight's tour game

We provide on Moodle a set of 10 instances to test your implementation. These instances are part of instances on which your implementation will be evaluated on INGINIOUS. Five (05) more hidden instances will be used.

One file is provided containing all the instances. Each line in the file represents an instance and will be passed individually to your implementation. The line representing an instance contains four (04) numbers described chronologically as following:

1. the number of rows of the board
2. the number of columns of the board
3. the position of the knight on rows axis
4. the position of the knight on columns axis

The solving of each instance involves the passing of the board through several states. We use utf-8 symbols in order to represent the tiles we see in Figure 1.

- visited tile :  *python: `u"\u265E"` — utf-8: `0xE2 0x99 0x9E`*
- not yet visited tile : space character
- current position of the knight :  *python: `u"\u2658"` — utf-8: `0xE2 0x99 0x98`*

Each tile is separated by a space character and the borders of the board are represented by # characters. The following configuration represents the grid of shape 5×5 with five moves already done by the knight and the current position is at index $[3][1]$

¹https://en.wikipedia.org/wiki/Knight%27s_tour

Figure 2: A state of Knight's tour problem

The output of the program should be a sequence of every intermediate grid, represented in the same way, starting with the initial state and finishing with the goal state. Figure 3 shows the solving process of instance: 5 5 1 1.

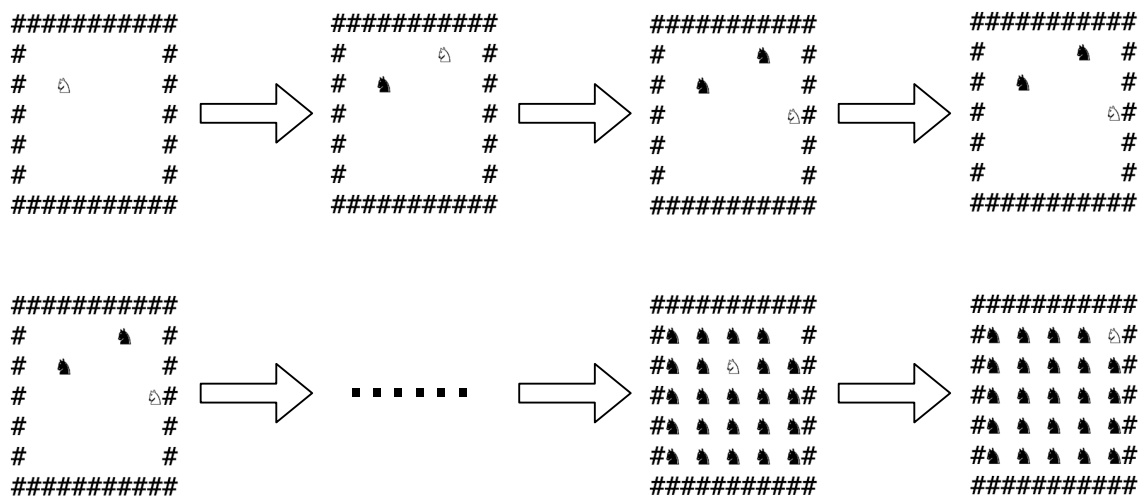

Figure 3: Solving process of instance : 5 5 1 1

You will implement at least one class *Knight(Problem)* that extends the class *Problem* such that you will be able to use search algorithms of AIMA. A small template (*knight.py*) is provided in the resources for this problem on moodle. Before diving into the code, we recommend you to first have a look at the questions below that need to be answered in your written report.

Questions

1. Describe the set of possible actions your agent will consider at each state. Evaluate the branching factor.
2. Problem analysis.
 - (a) Explain the advantages and weaknesses of the following search strategies **on this problem** (not in general): depth first, breadth first. Which approach would you choose?

- (b) What are the advantages and disadvantages of using the tree and graph search **for this problem**. Which approach would you choose?
3. **Implement** a Knight's tour solver in Python 3. You shall extend the *Problem* class and implement the necessary methods –and other class(es) if necessary– allowing you to test the following four different approaches:
- *depth-first tree-search (DFSt)*;
 - *breadth-first tree-search (BFSt)*;
 - *depth-first graph-search (DFSg)*;
 - *breadth-first graph-search (BFSg)*.

Experiments must be realized (*not yet on INGIInious!* use your own computer or one from the computer rooms) with the provided 10 instances. Report in a table the results on the 10 instances for depth-first and breadth-first strategies on both tree and graph search (4 settings above). Run each experiment for a maximum of 3 minutes. You must report the time, the number of explored nodes as well as the number of remaining nodes in the queue to get a solution.

4. **Submit** your program (encoded in **utf-8**) on INGIInious. According to your experimentations, it must use the algorithm that leads to the best results. Your program must take as inputs the four number previously described separated by space character, and print to the standard output a solution to the problem satisfying the format described in Figure 3. Under INGIInious (only 45s timeout per instance!), we expect you to solve at least 12 out of the 15 ones.
5. **Conclusion.** Do you see any improvement directions for the best algorithm you chose? (Note that since we're still in uninformed search, *we're not talking about informed heuristics*).
